

leetcode: 52.N-Queens II

Problem statement

The **n-queens** puzzle is the problem of placing n queens on an $n \times n$ chessboard such that no two queens attack each other.

Given an integer n , return *the number of distinct solutions to the n-queens puzzle*.

Example 1:

Input: $n = 4$

Output: 2

Explanation: There are two distinct solutions to the 4-queens puzzle as shown.

Example 2:

Input: $n = 1$

Output: 1

Constraints:

- $1 \leq n \leq 9$

Understand the problem

For a board of size 4x4, we have two solutions:

Main idea

See (Fig.1)

for a queen Q in row i , for all columns from 0 to $n-1$, check if we can not place another queen Q' in any column at row $i+1$, back to the previous row i and check if we can place the queen Q at another column.

We find a solution when we place the last queen in a valid column at row $n-1$.

Repeat all the above process until we check all configurations and every time we found a solution, display it.

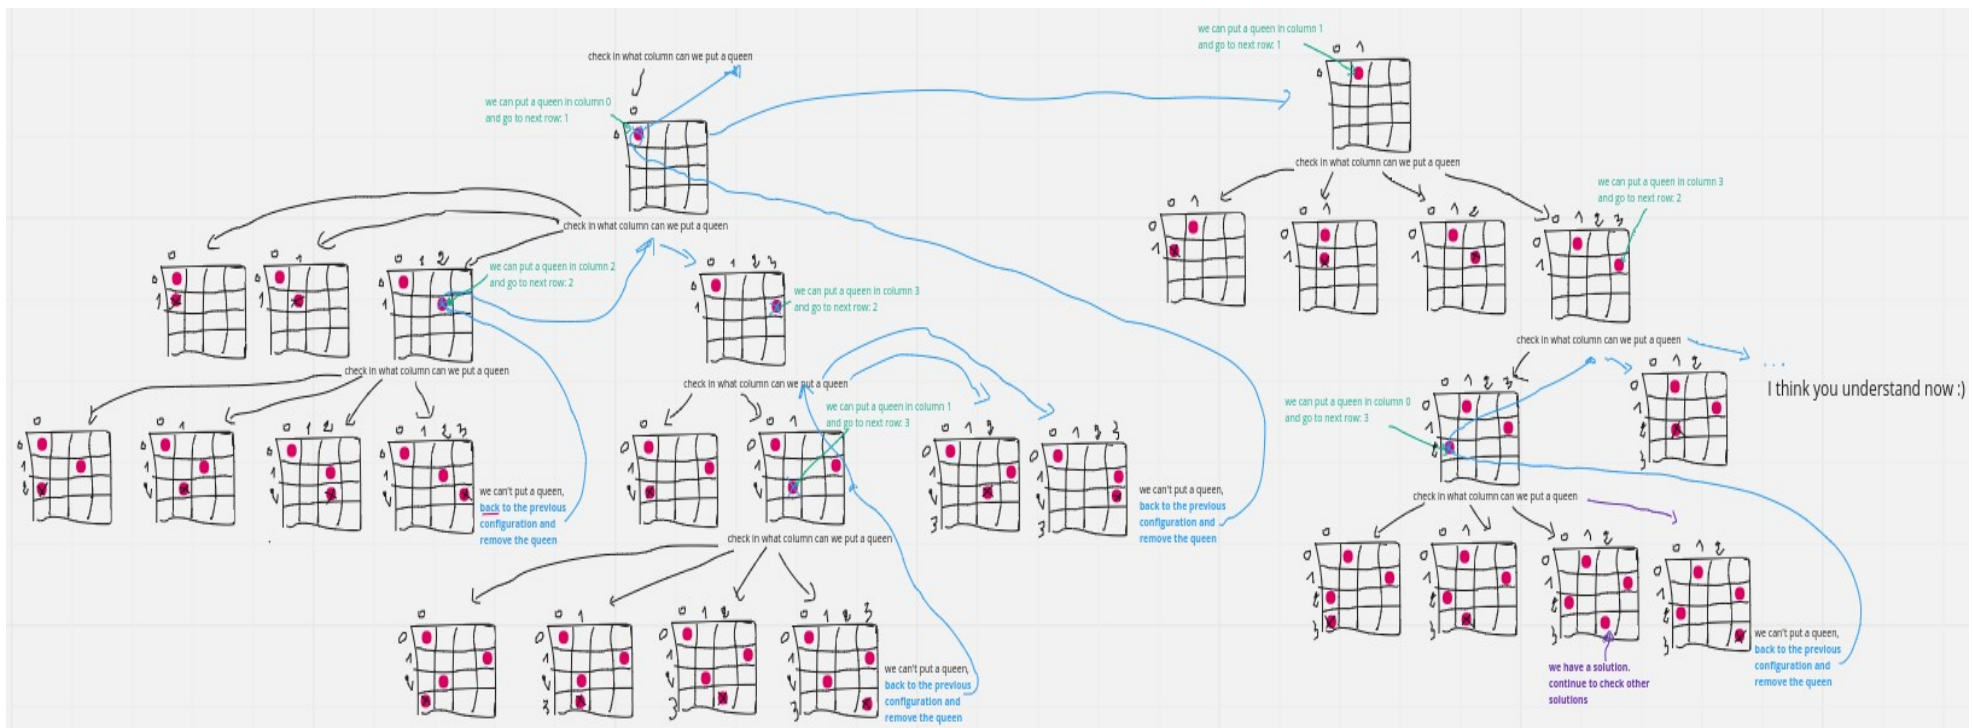

Fig.1

Part of the hand execution of the process

Pseudo code

We're going to use the power of non-terminal recursive function to do the backtracking. (**Fig.2**)

At row row , we're going to check if we can put a queen in any column from 0 to $n-1$.

If yes: check if we can put a queen in any column from 0 to $n-1$ for the next row $row+1$,

if no: it means the *for loop* is terminated, back to the previous call of the function $solve()$ and terminate it.

Fig.2

Part of the recursion tree

Same for if we find a solution, continue with the previous call.

At each base case and end of the *for loop* , the program will pop a call from the calls stack until all calls are terminated.

```

void solve(string board[][], int row, int col, int n) {
    // Base case
    // Remember that the last row is at  $n - 1$  , if row reach n that means we have a valid queen
    at //row  $n - 1$  .
    if (row == n) {
        ans++;

        // Backtracking: Trigger the last call of the function solve, goes to the previous configuration
        // No need to a return, but I don't know if it will works will all C++ compilers
        return;
    }

    // At the row row , check in which column, we can put a queen
    for cur_col  $\in [0, n-1]$  {
        if we can not put a queen in cell (row, cur_col), then go the the next column
        otherwise:
        put a queen in cell (row, cur_col)
        solve the next row: solve(board, row+1, cur_col) // go to next row
        remove the queen in cell (row, cur_col)
    }

    // Backtracking: Trigger the last call of the function solve, goes to the previous configuration
    // No need to a return, but I don't know if it will works will all C++ compilers
    return;
}

```

Now let's focus on how to know if we can put a queen at $cell(row, col)$?

Can we place a queen?: Naive approach

The obvious approach is to check:

- check the column col cells above the row row :
 $board[i][col]$, where $0 \leq i \leq row-1$ (Fig.3)
- check the diagonal cells above the row row :
 $board[i][j]$, where $0 \leq i \leq row-1$ and $0 \leq j \leq col-1$ (Fig.4)
- check the anti-diagonal cells above the row row :
 $board[i][j]$, where $0 \leq i \leq row-1$ and $col+1 \leq j \leq n-1$ (Fig.5)

Fig.3

Check if a queen exists in the column of the $cell(row, col)$

Fig.4

Check if a queen exists in the diagonal of the $cell(row, col)$

Fig.5

Check if a queen exists in the anti-diagonal of the $cell(row, col)$

this is the pseudo code of the function:

$$\text{we_can_put_a_queen}(\text{board}, \text{row}, \text{col}) = \begin{cases} \text{true, if there is no other queen} \in \text{column col and diagonal and anti-diagonal} \\ \text{false, otherwise} \end{cases}$$

```
we_can_put_a_queen(string board[][], int row, int col, int n){
    for i ∈ [0, row-1]{
        if board[i][col] == "Q" return false;
    }
    for i ∈ [row-1, 0, -1] and j ∈ [col-1, 0, -1] {
        if board[i][j] == "Q" return false;
    }
    for i ∈ [row-1, 0, -1] and j ∈ [col+1, n-1] {
        if board[i][j] == "Q" return false;
    }
    return true;
}
```

Time complexity is $O(n)$

space complexity is $O(n^2)$

Whole code: C++

```
#include <bits/stdc++.h>
/*
 * @lc app=leetcode id=52 lang=cpp
 *
 * [52] N-Queens II
 */

// @lc code=start
class Solution {
private:
    int ans = 0;

public:
    bool we_can_put_a_queen_in_column(int row, int col, int n, std::vector<std::vector<std::string>> board){
        // Check if a queen exists in same column
        // No need to check below the row
        for (int i = 0 ; i < row ; ++i)
            if (board[i][col] == "Q") return false;

        // Check if a queen exists in the diagonal of the given cell
        // No need to check the bottom side of the diagonal
        for(int i = row-1 , j = col-1 ; i >= 0 && j >= 0 ; --i,--j)
            if (board[i][j] == "Q") return false;

        // Check if a queen exists in the anti-diagonal
        // No need to check the bottom side of the diagonal
        for(int i = row-1 , j = col+1 ; i >= 0 && j < n ; --i,++j)
            if (board[i][j] == "Q") return false;

        return true;
    }

    void solve (std::vector<std::vector<std::string>> board, int row, int col, int n){
        if (row == n){
            ans++;
            return;
        }

        for (int cur_col = 0 ; cur_col < n ; ++cur_col){

            if (!we_can_put_a_queen_in_column(row, cur_col, n, board)) continue;

            board[row][cur_col] = "Q";

            solve(board, row + 1, cur_col, n);

            board[row][cur_col] = ".";
        }
        return;
    }
}
```

```

int totalNQueens(int n) {
    std::vector<std::vector<std::string>> board(n, std::vector<std::string>(n, "."));
    solve(board,0,0,n);
    return ans;
}
};
// @lc code=end

```

<https://github.com/Mourad-NOUAILI/leet-code/blob/main/52.%20N-Queens-II/52.n-queens-ii-bf.cpp>

The time complexity: $O(n \times n!)$

Space complexity is $O(n^2)$

We can improve the time complexity of the function `we_can_put_a_queen_in_column()` to $O(1)$

Let's see how.

Can we place a queen?: efficient approach

To be honest, I didn't figure out this solution, I found it in YouTube.

The principle is easy, if a queen exists in a cell, set 1 to a specific position in the **three bitmask** of the columns and/or diagonals and/or anti-diagonals, otherwise set it to 0 .

First let's remind some bit-wise manipulations.

- To know if the i^{th} bit of a number x is set or not, shift the digit 1 by i places to the left, then make a *bitwise AND* with x . $x \text{ AND } (1 \ll i)$

examples:

$$x = (12)_{10} = (0000\mathbf{1}100)_2$$

Is the bit #3 set in x ?

$$1 \ll 3 = 00000001 \ll 1 = 00001000$$

$$12 \text{ AND } 00001000 = 00001100 \text{ AND } 00010000 = 00010000 = 0001000 = (8)_{10}$$

result $\neq 0$, so the answer is yes.

Is the bit #5 set in x ?

$$x = (12)_{10} = (00\mathbf{0}01100)_2$$

$$1 \ll 5 = 00000001 \ll 1 = 00100000$$

$$12 \text{ AND } 00100000 = 00001100 \text{ AND } 00100000 = 00000000 = 0 = (0)_{10}$$

result = 0, so the answer is No.

- To set the i^{th} bit, shift the digit 1 by i places to the left, then make a *bitwise OR* with x . $x \text{ OR } (1 \ll i)$

Example:

Set the bit #5 in x ?

$$x = (12)_{10} = (00\mathbf{0}01100)_2$$

$$1 \ll 5 = 00000001 \ll 1 = 00100000$$

$$12 \text{ OR } 00100000 = 00\mathbf{0}01100 \text{ OR } 00100000 = 00\mathbf{1}01100 = (44)_{10}$$

- To flip the i^{th} bit, shift the digit 1 by i places to the left, then make a bitwise XOR with x . $x \text{ XOR } (1 \ll i)$

Example:

Flip the bit #5 in $x = (12)_{10}$?

$$x = (12)_{10} = (0001100)_2$$

$$1 \ll 5 = 00000001 \ll 1 = 00100000$$

$$12 \text{ XOR } 00100000 = 0001100 \text{ XOR } 00100000 = 00101100 = (44)_{10}$$

How can this be helpful?

For a $n \times n$ board:

- column n refer to LSB and column 0 refer to MSB,
- diagonal $2n-1$ refer to LSB and diagonal $2(n-1)$ refers to MSB
- anti-diagonal 0 refers to LSB and anti-diagonal $2(n-1)$ refers to MSB

Example: n=4

The figures (Fig.6, Fig.7 and Fig.8) show respectively how to attribute the bits of the bitmasks of the columns, the diagonals and the anti-diagonals.

Fig.6

Column #0 refers to LSB
Column #3 refers to MSB

Fig.7

Column #7 refers to LSB
Column #6 refers to MSB

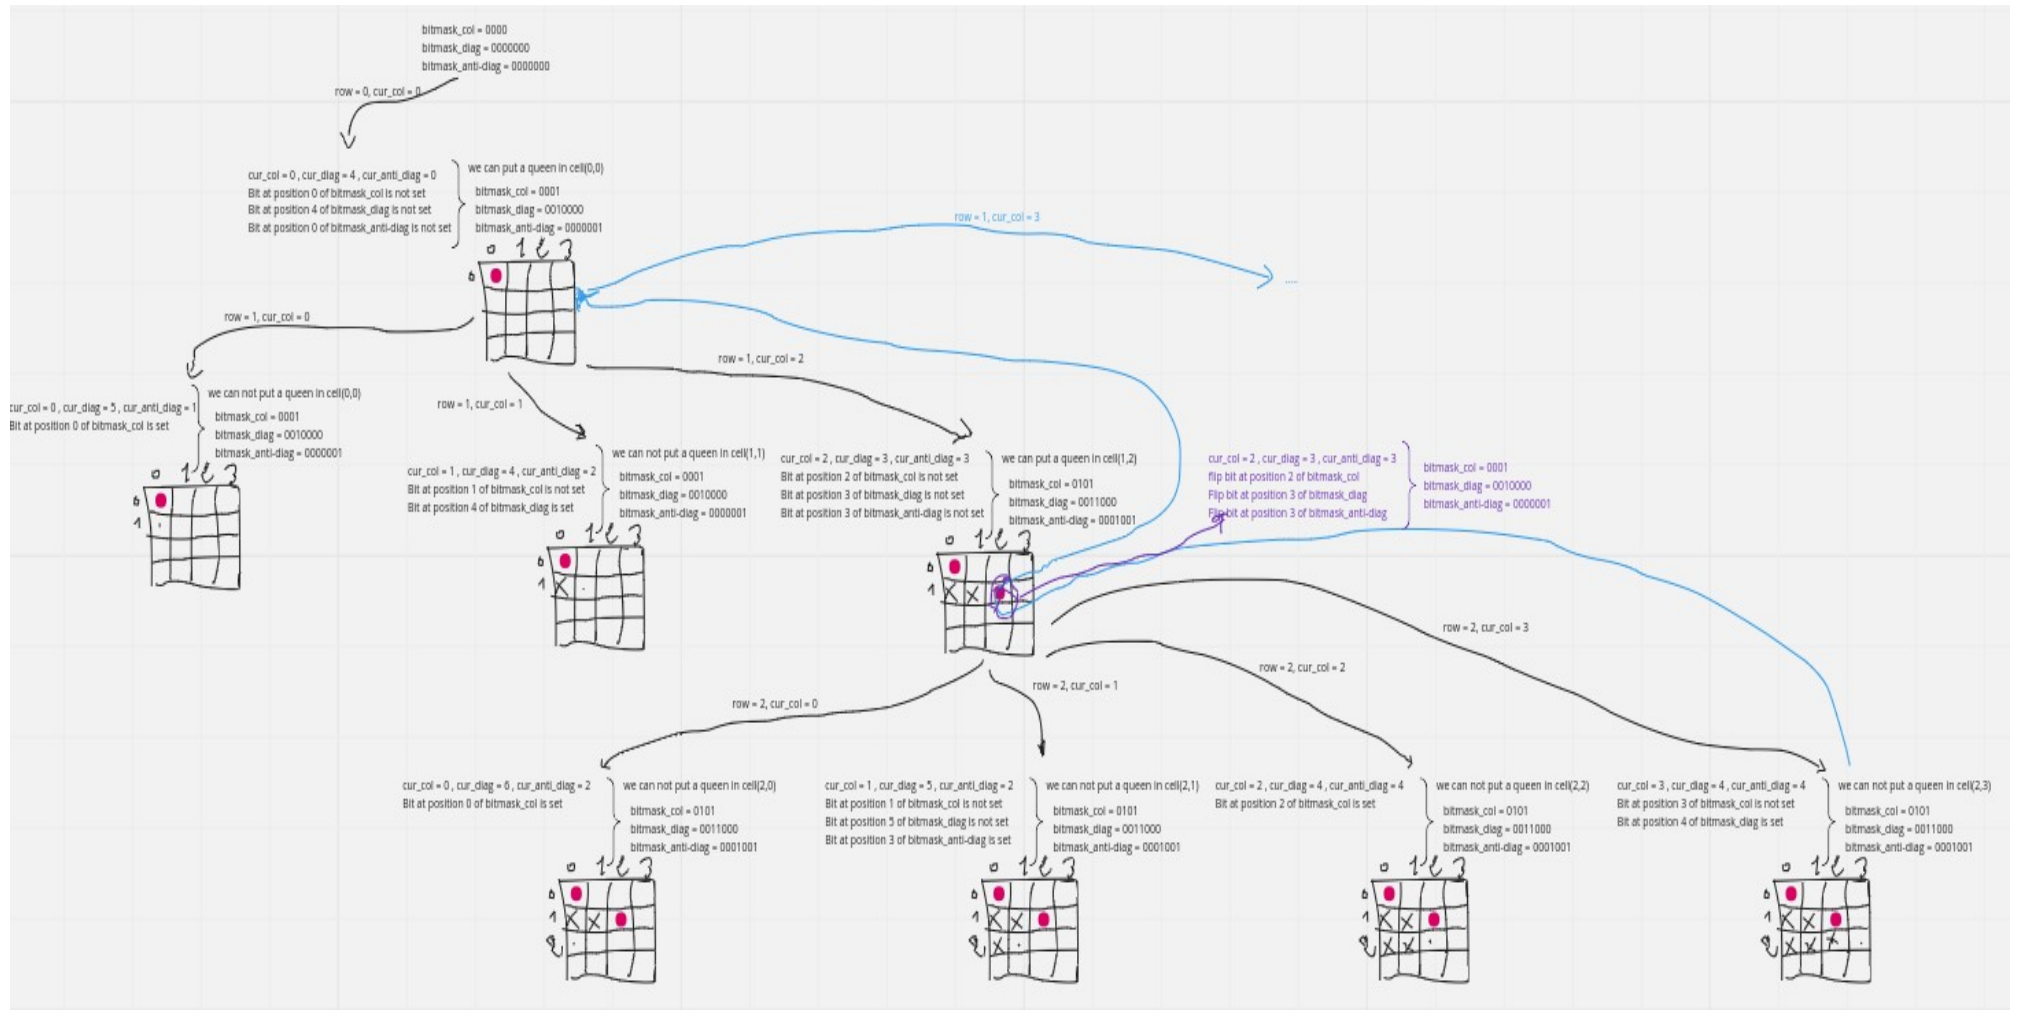

Fig.8

Column #0 refers to LSB
Column #6 refers to MSB

To understand more, let's draw a part of the recursion tree for a 4×4 board:

Whole code: C++

```
#include <bits/stdc++.h>
/*
 * @lc app=leetcode id=52 lang=cpp
 *
 * [52] N-Queens II
 */
// @lc code=start
class Solution {
private:
    int ans = 0;

public:
    void solve(int row, int bitmask_col, int bitmask_diag, int bitmask_anti_diag, int n){
        if (row == n){
            ans++;
            return;
        }
        for (int cur_col = 0 ; cur_col < n ; ++cur_col){
            int cur_diag = row-cur_col+n;
            int cur_anti_diag = row+cur_col;
            if ( (bitmask_col & (1 << cur_col)) != 0 || (bitmask_diag & (1 << cur_diag)) != 0 || (bitmask_anti_diag & (1 << cur_anti_diag)) != 0 ) continue;
            bitmask_col |= (1 << cur_col);
            bitmask_diag |= (1 << cur_diag);
            bitmask_anti_diag |= (1 << cur_anti_diag);

            solve(row + 1, bitmask_col, bitmask_diag, bitmask_anti_diag, n);

            bitmask_col ^= (1 << cur_col);
            bitmask_diag ^= (1 << cur_diag);
            bitmask_anti_diag ^= (1 << cur_anti_diag);
        }
        return;
    }
    int totalNQueens(int n) {
        solve(0,0,0,0,n);
        return ans;
    }
};
// @lc code=end
```

Time complexity: $O(n!)$, Space complexity: $O(1)$
